## Problem A. Ball momentum

| Input file: | standard input |
| :--- | :--- |
| Output file: | standard output |
| Time limit: | 1 second |
| Memory limit: | 256 megabytes |

There are $n$ baseball balls and $n$ machines for serving them. Each ball has its weight $w_{i}$ and each machine has its power of serving $p_{i}$. We can choose a ball and machine to serve it. Let's say that difficulty of catching $i$-th ball served using machine $j$ is $w_{i} \times p_{j}$. You want to pick a pair $(i ; j)$ such that any other pair $\left(i^{\prime} ; j^{\prime}\right)\left(i \neq i^{\prime}\right.$ and $\left.j \neq j^{\prime}\right)$ has difficulty of catching less or equal to the difficulty of catching the pair $(i ; j)$. Tell the number of such pairs.

## Input

The first line of input contains a single integer $n\left(1 \leq n \leq 2 \cdot 10^{5}\right)$ - number of balls and serving machines.
The second line of input contains $n$ integers $w_{i}\left(1 \leq w_{i} \leq 10^{9}\right)-$ weitghts of balls.
The third line of input contains $n$ integers $p_{i}\left(1 \leq p_{i} \leq 10^{9}\right)$ - powers of serving machines.

## Output

Print one integer - answer to the problem.

## Scoring

1. (7 points): $n \leq 3$;
2. ( 7 points): all $w_{i}$ are equal and all $p_{i}$ are equal;
3. ( 8 points): all $w_{i}$ are equal;
4. (9 points): $w_{i}, p_{i} \leq 1000 ;$
5. (23 points): $n \leq 100$
6. (24 points): $n \leq 1000$
7. (22 points): no additional restrictions.

## Problem B. Typical Query Problem

Input file:
Output file:
Time limit:
Memory limit:
standard input
standard output
1 second
256 megabytes

You are given two integers $C$ and $L$ and array $a$ consisting of $n$ integers. You are given $q$ queries of format $\operatorname{lr} x$. After each query, you have to:

1. subtract $x$ from all elements on a segment $[l ; r]$ of array $a$;
2. tell whether there exist a good segment $S$ on the array $a$. A segment $S$ is considered good if $\operatorname{len}(S) \geq L$ and $\operatorname{avg}(S) \leq C$, where $\operatorname{len}(S)$ denotes the length of the segment $S$ and $\operatorname{avg}(S)$ denotes the average value on segment $S$.

## Input

The first line of input contains four integers $n, L\left(1 \leq L \leq n \leq 2 \cdot 10^{5}\right), q\left(1 \leq q \leq 2 \cdot 10^{5}\right), C$ $\left(-10^{9} \leq C \leq 10^{9}\right)$.
The second line of input contains $n$ integers $a_{i}\left(-10^{9} \leq a_{i} \leq 10^{9}\right)-$ given array $a$.
The following $q$ lines contain three integers $l, r(1 \leq l \leq r \leq n), x\left(0 \leq x \leq 10^{7}\right)$ each - description of the queries.

## Output

Print $q$ lines, each consisting of YES, if there exists a good segment $S$, or NO otherwise.

## Scoring

1. (11 points): $n \leq 3$;
2. (12 points): $n \leq 100, q \leq 1000$;
3. (14 points): $q=1, C=0$;
4. (15 points): $C=0$;
5. (19 points): $q=1$;
6. (29 points): no additional restrictions.

## Example

|  |  |  | standard input |  | standard output |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 4 | 2 | 3 | 2 |  | NO |
| 5 | 6 | 3 | 4 |  | NO |
| 1 | 2 | 2 | YES |  |  |
| 1 | 3 | 1 |  |  |  |
| 1 | 4 | 2 |  |  |  |

## Problem C. Tree queries

Input file:
Output file:
Time limit:
Memory limit:
standard input
standard output
1 second
256 megabytes

You are given a connected graph with $n$ vertexes and $n-1$ edges. In other words, you are given a tree. Vertex 1 is the root of the tree. In vertex $v$ there is an integer $a_{v}$ written on it. Let's define cost of the tree as XOR sum of all its values. You were given $q$ queries, containing two integers $v$ and $x$. Each query makes $a_{u}=a_{u} \oplus x$, where $u$ belongs to the subtree of the vertex $v$ and $\oplus$ denotes XOR operation. As we all know, this problem can be easily solved by our participants, but if all was that easy, this problem wouldn't appear at this Olympiad. You know that some queries were changed by angry Anton. Thus, you are asked to find the sum of costs modulo 998244353 , of all $2^{q}$ trees that can be obtained by applying some (possibly none) queries on the tree.

## Input

The first line of input contains two integers $n\left(1 \leq n \leq 2 \cdot 10^{5}\right)$ and $q\left(1 \leq q \leq 2 \cdot 10^{5}\right)$ - number of vertexes in the tree and number of queries accordingly.
The second line of input contains $n$ integers $a_{i}\left(0 \leq a_{i}<2^{60}\right)$ - values written on the vertex of the tree. The following $n-1$ lines contain two integers $u$ and $v$ each - edges of the given tree.
The following $q$ lines contain two integers $v(1 \leq v \leq n)$ and $x\left(0 \leq x<2^{60}\right)$ each - description of queries.

## Output

Print one integer in the first line - answer to the problem.

## Scoring

1. (7 points): $q \leq 2$;
2. (12 points): $q \leq 10$;
3. (16 points): $q \leq 20$;
4. (18 points): $a_{i}, x<2$;
5. (13 points): $a_{i}, x<1024$;
6. ( 15 points): $a_{i}, x<2^{18}$;
7. (19 points): no additional restrictions.

## Example

|  | standard input |  | standard output |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 5 | 3 |  |  | 28 |  |
| 1 | 0 | 2 | 3 | 1 |  |
| 1 | 2 |  |  |  |  |
| 1 | 3 |  |  |  |  |
| 3 | 4 |  |  |  |  |
| 3 | 5 |  |  |  |  |
| 3 | 2 |  |  |  |  |
| 4 | 3 |  |  |  |  |
| 1 | 5 |  |  |  |  |

## Problem D. Anton the Guard

Input file: standard input<br>Output file: standard output<br>Time limit:<br>Memory limit<br>3 seconds<br>256 megabytes

Anton is a security guard responsible for $n$ objects numbered from 1 to $n$. There are also $n-1$ roads, where the $i$-th road connects objects $u_{i}$ and $v_{i}$ and has a length of $w_{i}$.
At the beginning, Anton is located at object 1 .
Let's define the priority of each object as the minimum number of roads that need to be traveled from this object to object 1 . For example, for object 1 this number will be 0 ; for all objects directly connected to 1 , it will be 1 , and so on.
Anton needs to visit all objects. He needs to first visit all objects that have a priority of 1 , then those that have a priority of 2 , and so on. If there are several objects with the same priority, Anton can choose the order in which to visit them. Note that he can only visit any object with priority $k$ after he has visited all objects with priority $k-1$.

Find the minimum distance that he will have to travel.

## Input

The first line contains an integer $n\left(1 \leq n \leq 10^{6}\right)$.
The second line contains $n-1$ integers $p_{i}$ which indicate that there is a road from object $i+1$ to object $p_{i}\left(1 \leq p_{i} \leq n\right)$.
The third line contains $n-1$ integers $w_{i}$ which are the lengths of roads between objects $i+1$ and $p_{i}$ $\left(1 \leq w_{i} \leq 10^{9}\right)$.
It is guaranteed that it is possible to reach all other objects from object 1.

## Output

Output a single integer - the answer to the problem.

## Scoring

1. (4 points): $1 \leq n \leq 10$;
2. (5 points): $1 \leq n \leq 22$;
3. (13 points): no more than 6 objects have the same priority;
4. (10 points): no more than 10 objects have the same priority;
5. (15 points): $w_{i}=1$;
6. (15 points): $1 \leq n \leq 10^{5}$;
7. (38 points): without additional restrictions.
